#Travis

Cleanflight provides Travis build and config files in the repository root.

Pushing builds to a remote server

`.travis.sh` script can upload build artifacts to a remote server. This feature is controlled by the
PUBLISH_URL environment variable. If set, the build script will use the cURL binary and simulate a file upload post to the configured server.

Pleas check the `notifications` section in the `.travis.yml` file and adjust the irc notifications if you plan on using Travis on your Cleanflight fork
